Determinants of Indonesian Share Price: Do Capital Structure, Sales Growth, and Profitability Matter?

Nicodemus Simu and Anneke Margaret Pangaribuan

Asian Banking Finance and Informatics Institute Perbanas, Jakarta, Indonesia

Abstract

This research is aiming at discovering the direct and indirect effects of capital structure and sales growth on share price with profitability as the mediating variable. This research studied 26 companies listed in LQ45 index from 2016–2017. They were selected by using purposive sampling method. Fifty-two observation data were analyzed using path analysis. The hypothesis testing on the first substructure equation results in the conclusion that both capital structure and sales growth have no significant effects on profitability. On the second substructure equation, capital structure and sales growth also have no significant effects on share price. However, profitability has significant positive effects on share price. By using Sobel test, the mediating effects of profitability on the effects of capital structure and sales growth on share price could not be confirmed.

Keywords: capital structure, sales growth, profitability, share price

I. INTRODUCTION

Share price is an indicator to measure the corporate management performance. The price reflects the tug of war between investors in their bids and asks for the share price. In general, a company’s share price reflects investors’ perception of the company’s value. The higher a company’s share price is, the better the investors’ perception of the company is. On the other hand, a low share price which tends to decrease reflects the poor performance or imperfect reputation of the company. A shareholder who is dissatisfied with the company’s performance can sell his shares and invest the money to another company. This condition may be communicable to other shareholders which cumulatively can put selling pressure to the company’s shares, and eventually it causes the share price to fall.

Share price becomes important to investors as it has economic consequences. Changes in share price can alter the market value which also change the investors’ opportunities in the future. Share price is set based on the supplies and demands in the market. Demands of shares are influenced by investors’ expectation of the share issuer (the company). The better the performance of the share issuer, the higher the expectation of the investors is. This causes the company’s share to be attractive, and its price become increasingly high. Conversely, when the company’s financial performance is not good, the investors’ expectation becomes low, and investors are not attracted to invest in the shares. In a nutshell, share price becomes an indicator of investors’ expectation of a company’s performance and its potential improvement in the future. Generally, there are some internal and external factors which affect the tug of war over the (potential) investors’ supplies and demands which influence the share price. The internal factors are the price influencing factors source from within a company, whereas the external factors are those price influencing factors originating from outside the company.

This present research focuses on the effects of the internal factors on the dynamics of share price movements which are directly and indirectly mediated by other internal factors. The internal factors are capital structure, sales growth, and profitability level. Capital structure shows the financing sources of a company. A company which use borrowed capital to fund its productive investments can have positive outcomes because the company’s leverage can multiply their income to a higher level in comparison with the incurred fixed cost from the borrowed capital (Tally, 2014). The positive outcomes are the increase of earnings and the rise of the share price. These outcomes also signify an increase in the shareholders’ well-being (Tani, 2012). On the other hand, negative outcomes are inevitable when the company cannot balance the increasing debts with productive investment, or, worse still, the increasing debts becomes counterproductive burden on the company’s finance. Previous research by Onyema and Oji (2018) concluded that financial leverage has no significant effects on profitability. In addition, high leverage reflects higher risks to the company itself; thus, investors tend to avoid investing in companies with high financial leverage (Bailia, Tommy, & Baramuli, 2016).

Sales growth, an output of a company’s performance in the past, can be in the forms of investment in fixed assets and sales capacity. Therefore, sales growth data can be used to predict sales growth in the future (Clarenisnia, Rahayu, & Azizah, 2012; Chandra & Veronica, 2018). A constant increase of sales growth is an indicator that a company still has the opportunity to achieve higher performance level and better prospects (Hayati, Simbolon, Situmorang, Haloho,
A high level of sales is a basic indicator that a company can increase its profitability which can motivate the investors’ interests in buying the company’s shares (Chandra & Veronica, 2018).

Profitability indicates whether a company’s performance is good or bad (Utami & Prasetiono, 2016). A good performance of a company can attract investors to invest their money (Alipudin & Oktaviani, 2016), and this can affect the fluctuation of the company’s share price (Vonna, Islahudin, & Musnadi, 2016).

II. LITERATURE REVIEW & HYPOTHESIS

A. Capital Structure and Profitability

Capital structure of a company is related to the decisions to develop its policies on sources of capital funding. Kipesha and Moshi (2014) are of the opinion that the decision on using a particular source of funding can have different effects on the company’s performance. Thus, the company must try to formulate the best combination of debt and equity to maximize the company’s market value (Vouggaris, Asteriou, & Agiomirgianakis, 2002). In other words, capital structure involves an important funding policy which generally can affect the earnings performance or can be used to maximize the shareholders’ well-being (Onyema & Oji, 2018). A company uses debts to finance its investment, its expenses, and its efforts to increase sales. The financing policy of a company manifested in the amount of DER implicitly indicates the amount of the company’s liabilities in terms of principal payment and interest expenses which cumulatively becomes financial liabilities and affects the amounts of the company’s earnings.

Previous research has confirmed that a financing policy which is suitable for a company may not be suitable for others (Onyema & Oji, 2018). For a company, a higher debt ratio in its capital structure can yield profitable results when the company gains positive difference because the economic rentabilty level of the company is higher than the interest level of its debts. In this case, using borrowed capital is more favorable and can give more value added which is more profitable for the shareholders. In other words, when the economic situation is good, a greater use of debts can increase profitability, and the increase of capital structure can affect a company’s financing performance which increases the company’s earnings (Felany & Worokiniasih, 2018). Based on the opinion, the following hypothesis needs to be tested:

$H_1$: Capital structure has a significant positive effect on profitability.

B. Sales Growth and Profitability

Sales is the main operation and source of income for a company which relies on the sales to generate earnings. Sales growth is the increase of current sales from the previous year’s sales stated in percentage (Carvalho & Costa, 2014). High sales level is basically a metric to indicate market penetration level of the company’s products, and it is usually followed by significant sales growth. Therefore, sales growth reflects the company’s success in its investment in previous period, and it can be used to predict the company’s growth in the future (Sambharakreshna, 2010; Clarenisiaet al., 2012; Chandra & Veronica, 2018).

By identifying the sales growth quantity, a company can predict the amount of earnings it will have. A good sales growth can stimulate improvement of the company’s profitability. Previous research by Ali, Hussin, and Ghani (2019) concluded that an increase of sales growth can moderately increase profitability measured by ROA, and, in general, continuous sales growth can affect return on equity. This conclusion is in line with those of Shintya, Situmorang, and Iryani (2017) and Suryaputra and Christiawan (2016) which state that sales growth has a significant positive effect on profitability. Thus, the hypothesis is formulated as follows.

$H_2$: Sales growth has a significant positive effect on profitability.

C. Capital Structure and Share Price

Capital structure is basically a company’s financial framework which combines debt and equity capital of the company (Uwalomwa & Uadiale, 2012). The capital structure of a company is shown by comparing its total debts to the total shareholders’ equity or commonly known as the debt to equity ratio (DER).

A company has the freedom of choosing the most suitable capital structure which can increase its share price (Andow & Wetsi, 2018). However, it is important to note that capital structure is also an indicator of a company’s financial risks. When a company uses a bigger amount of borrowed capital for its operations which means it has a higher capital structure ratio, it faces higher financial risks because of the intensity of cash outflow for loan principal payment and for interest expense payment.

When a company’s long-term loan is getting bigger, the company may face potential liquidity disruptions in the future. The disruptions emerge because the company places a higher priority on using its earnings to pay the loan and its interests, rather than using the earnings to pay dividends (Alipudin & Oktaviani, 2016). When this happens, the share price of the company may come under pressure, and, eventually, it will have an effect on the investors’ lack of interests to buy the shares. This statement is confirmed by Widayanti and Colline (2017) and Andow and Wetsi (2018). Thus, the hypothesis to be tested is as follows.
**H1:** Capital Structure has a significant negative effect on share price

**D. Sales Growth and Share Price**

A company with high sales growth will be able to fulfill its financial obligations (Clarensia et al., 2012). It is generally accepted that high sales growth affects the increase of the company’s earnings which can motivate the investors’ intention to buy the company’s shares. In other words, the company’s growth measured by the sales growth can affect the company’s value or its share price because the company’s growth indicated positive improvement of the company which will receive positive responses from the investors (Bailia et al., 2016).

A company’s sales growth shows the company’s condition externally. The rise of a company’s sales growth indicates the company runs its operation properly. The company’s ability to run a business properly gives a positive signal to the investors that it has good prospects in the future (Chandra & Veronica, 2018). If the company’s sales growth keeps on increasing annually, the company has the prospects of surviving and successful because sales growth affects the increase of earnings and will draw the investors’ interests to buy its shares (Clarensia et al., 2012). Thus, the hypothesis to be tested is as follows.

**H2:** Sales growth has a significant positive effect on share price.

**E. Profitability and Share Price**

Profitability is a company’s ability to generate earnings. Profitability is also a measurement of efficiency because the higher the profitability of a company is, the more efficient the company uses its assets (Alipudin & Oktaviani, 2016). Profitability is the company’s main appeal in order to attract potential investors who are ultimately concerned about current earnings, future earnings, and earnings stability. In this case, investors must really take profitability into consideration because it determines the company’s prospects. Every company will always try to increase its performance and generate great earnings which enable the company to continue its operations and to grow. For investors, high profitability of a company is a signal that the company’s operations, investments, and financing are well-managed. This will eventually increase the company’s share price, and directly increase the company’s value (Barakat, 2014).

Consistent reports on high earnings for some periods can attract investors to buy the company’s shares. That is why profitability is considered as one of the internal factors which affects the level of attractiveness of certain shares because their profitability indicates the productivity of the company’s assets to generate earnings (Chandra & Veronica, 2018). When some investors think that a share is attractive and worthy to be invested in, there will be buying pressure which eventually can increase the share price. In other words, the increase of profitability indicates the company’s financial performance is good, and its share price will also increase. Based on this explanation, the hypothesis to be tested can be formulated as follow.

**H3:** Profitability has a significant positive effect on share price

**F. Profitability Mediates the Effect of Capital Structure on Share Price**

Capital structure of a company influences its profitability. An increase in capital debts followed by returns which are higher than the incurring interest expenses will directly increase the company’s net income and, of course, its earnings. High earnings indicate the company is efficiently well-managed. This will be the reason why (potential) investors are attracted to invest their money in the company, and, this interests in buying the shares can boost the share price. From the brief explanation, it is suggested that profitability can mediate the influence of capital structure on share price. Thus, the hypothesis to be tested is as follows.

**H4:** Profitability mediates the effect of capital structure on share price

**G. Profitability Mediates the Effect of Sales Growth on Share Price**

Sales growth reflects the investment success in the previous period, and it can be used to predict the sales growth in the next period. The high level of sales growth reached by a company is one of the indicators that the company is able to run its operations properly. The increase in sales growth of a company which is balanced with the increase of current year earnings is a positive indicator which can motivate the investors to buy the company’s shares which, eventually, increases the share price. Based on the brief explanation, the hypothesis to be tested is formulated as follows.

**H5:** Profitability mediates the effect of sales growth on share price

**III. RESEARCH METHOD**

The research populations were companies listed in LQ45 index of Indonesia Stock Exchange from 2016–2017 (four publication periods). The purposive sampling method was used to select the samples with five criteria: companies which were consistently listed in LQ45 stock category from 2016–2017; companies which were regularly published their audited financial statements from 2016–2017; companies which did not perform corporate action of stock repurchase from 2016–2017; companies which did not belong to the category of the service companies or banking companies; and companies which did not generate negative earnings from 2016–2017. Based on the sampling criteria, there were 26 companies selected as the samples. The data were collected annually; thus, it created 52 observation data.
The present research is a quantitative research using secondary data from the companies’ stock reports and annual reports. The data were analyzed by using the multiple linear regression statistical technique to test the influence significance of the independent variables on the dependent variable. In addition, the data were also analyzed using the path analysis to test the direct and indirect influence of the exogenous variable on the endogenous variable through the endogenous mediating variable. The path analysis was also used to measure the direct and indirect relationships between variables in the model.

Based on the hypothesis development, Figure 1 illustrates the conceptual framework of this present research.

Table 1 summarizes the variables used in this present research, their operational definitions, types, and the measuring indicators.

**Table 1: Operational Variables**

<td>The relative proportion of total liabilities and common stock equity used to finance the firm’s total assets.</td>
<td>Exogenous variable</td>
<td>DER = Total Debt / Total Equity</td>
</tr>
<tr>
<td><strong>Sales Growth (SG)</strong></td>
<td>The increased sales and services between the current and previous year in percentage.</td>
<td>Exogenous variable</td>
<td>SG = Sales&lt;sub&gt;t&lt;/sub&gt; - Sales&lt;sub&gt;t-1&lt;/sub&gt; / Sales&lt;sub&gt;t-1&lt;/sub&gt;</td>
</tr>
</tbody>
</table>

The present research used path analysis which is an extension of multiple linear regression analysis used to predict the causality relationship between the variables which had been determined based on the theory. The data were processed using Eviews 9.

The first substructure equation is presented as follows.

\[
\text{ROA} = \beta_0 + \beta_1 \text{DER} + \beta_2 \text{SG} + \varepsilon_1
\]

Where:
- ROA = Profitability
- DER = Capital Structure
- SG = Sales Growth
- \(\beta_0\) = Constant term
- \(\beta_1, \beta_2\) = are slope to be estimated
- \(\varepsilon_1\) = Component unobserved error term

The second substructure equation is as follows.

\[
\text{SP} = \beta_0 + \beta_1 \text{DER} + \beta_2 \text{SG} + \beta_3 \text{ROA} + \varepsilon_2
\]

Where:
- SP = Share Price
- DER = Capital Structure
- SG = Sales Growth
- ROA = Profitability
- \(\beta_0\) = Constant term
- \(\beta_1, \beta_2, \beta_3\) = are slope to be estimated
- \(\varepsilon_2\) = Component unobserved error term

**IV. RESULTS AND DISCUSSION**

The descriptive statistics of the first and second substructures are summarized in Table 2.

**Table 2: Descriptive Statistics**

</table>
The results of descriptive statistics of the 52 observation data as shown in Table 2 describe the movements of each variable which becomes the subject of this present research. The summary of each variable is explained briefly as follows.

First, the share price mean of the observed companies from 2016–2016 is 8.1572, and the price range is between 6.1903 (minimum price) and 10.9313 (maximum price). The standard deviation is 1.078705. By examining the movements of price which is rather tight, and the standard deviation which is close to 0, it can be concluded that the observed shares had not been confirmed as shares with high liquidity. The shares are supposed to be listed in LQ45 which is an index of 45 shares which meet several criteria, two of which are the intensity of the trading days and/or the frequency of transactions.

Second, the mean of DER is 46.4734, and the standard deviation is 44.4566. The maximum DER is 188.2200 as attained by PT WaskitaKarya in 2017. The minimum DER is 0.0000 which was attained by PT MatahariDepartemen Store in 2016 and PT PF London Sumatra Indonesia in 2017. This minimum DER at 0.0000 indicates that both companies did not use any borrowed capital in financing their operations.

Third, the sales growth of the observed companies range from -23.0000 to 110.6000, and the mean of growth is 9.96346%. The highest sales growth was booked by PT JasaMargaPersero in 2017. The data also shows a company, PT AKR Corporindo, which gained negative growth in 2016. However, with standard deviation at 27.0501, it is normally considered that the entire sales growth is in positive level. In other words, even though the sales growth shows very high variations, the 26 observed companies still demonstrate the performance of companies with big capitalization which can still maintain positive sales growth.

Fourth, the mean of ROA is 10.4875, and the standard deviation is 10.5936. The maximum ROA is 46.1700 which was booked by PT MatahariDepartemen Store in 2016 which also reported 0% debts in its capital structure in the same year. This means the lower debts (%) might cause the company to gain the highest ROA in that period. On the other hand, the minimum ROA of 1.2000 was attained by PT LippoKarawaci in 2017. This result is relevant because the company had big capitalization. In general, it is proved that all the observed companies’ shares are still valid to be used as investment instruments as they can still generate earnings.

The assumption generated by multiple linear regression analysis must be tested by using the Jarque-Bera test to test the data normality, centered VIF to test multicollinearity, Glejser test to test heteroscedasticity, and Durbin-Watson test to test the autocorrelation. Using E-views, the test results show the data are quite sufficient to generate regression equations with fairly accurate estimation, unbiased, and consistent.

The use of E-views in processing data requires that Chow test, Hausman test, and Lagrange Multiplier test were undergone to determine the accuracy of one of the models, i.e. common effect (CE), fixed effect (FE), or random effect (RE), which would be used. The results show that the fixed effect model is more suitable to be used for the first substructure equation, whereas the random effect model is more suitable to be used for the second substructure equation.

The results of the data processing are shown in Table 3 and Table 4 to create regression equation in accordance with path analysis.

</tr>
<tr>
<td>SG</td>
<td>0.0028</td>
<td>0.0026</td>
<td>1.0906</td>
<td>0.2862</td>
</tr>
</tbody>
</table>

The regression equation for the first substructure is formulated as follows.

\[ \text{ROA} = 1.8261 + 0.0018 \text{DER} + 0.0028 \text{SG} \]

The first hypothesis states that capital structure has a significant positive effect on profitability. Some studies suggest that when DER value increases, ROA also increases. This means that the companies with massive borrowed capitals are able to manage their business properly so that they can yield great earnings as shown by the increase of their ROA. In Table 3, DER coefficient is 0.0018, and the Prob. is 0.6398. This indicates that although the coefficient value is positive, the first hypothesis is rejected because Prob. > 0.05. This means capital structure has no significant effect on profitability.

Companies’ financing policies which are reflected in their debt equity to ratio (DER) can influence the amount of earnings gained by the companies. The companies which become the objects of this research belong to several sectors, one of which is property sector which has a typical of an industry that uses debts as the major source of its capital. The use of debts which incur higher expenses than the cost of equity will motivate the increase in weighted average cost of capital. If this happens, a company will have to pay much bigger expenses to cover the company’s liabilities, particularly the long-term debts. The condition becomes the burden for the company and reduces its profitability.

The second hypothesis states that sales growth has a significant positive effect on profitability. The data in Table 3 shows SG coefficient is 0.0028, and the Prob. is 0.2862 which is > 0.05. This indicates that the
effect of SG on profitability is positive but insignificant. Thus, the second hypothesis is rejected.

Sales growth, basically, can be used as the basis for a projection of the total of profits that will be gained in current year earnings with an assumption that good sales growth can boost an increase in earnings. Nonetheless, sales growth is not an independent variable as it may influence or be influenced by other factors. In general, the consequence of sales growth is an increase of expenses used to achieve the sales growth, such as development costs, promotion costs, or distribution costs, not to mention the possible costs for purchasing certain assets driven by necessity.

This present research shows that sales growth is not the main factor for the increase in profitability. On one side, sales growth can boost an increase in profitability. On the other hand, the increase in profitability is proved to be achieved by paying for all the incurring expenses. In the end, the projected potential profitability decreases to a lower level.

Table 4: Panel Data Regression of the Second Substructure

<table>

<td>0.0293</td>
<td>0.0115</td>
<td>2.5354</td>
<td>0.0145</td>
</tr>
</tbody>
</table>

The regression equation for the second substructure is as follows.

\[
\text{Share Price} = 7.8102 + 0.0016 \times \text{DER} - 0.0018 \times \text{SG} + 0.0293 \times \text{ROA}
\]

In Table 4, DER is 0.0016 with Prob. 0.4926. The third hypothesis states that DER (capital structure) has a significant negative effect on share price. The Prob. 0.4926 is much higher than the 0.05 parameter. This indicates that capital structure has no significant effect on share price. Thus, the third hypothesis is rejected because it is proved that investors did not use capital structure as one of the determinants of the decision to invest in certain companies’ shares.

A company’s DER is a comparison of its leverage level (total debts use) with its total equity (its own capital). When DER is higher than 1.00, it indicates the total debts is higher than the equity. In general, DER value can indicate the extent of efforts done by the company management to develop its business in order to increase earnings or to maximize the company’s value. If investors believe in this perception, their interests to invest will become higher. This will increase their buying transactions which eventually increase the share price. On the other hand, a high DER value also reflects the amount of the company’s liabilities and shows that the company relies on external capital sources. This increases the risks faced by investors because of the incurring interest expenses which have to be paid by the company. The risks reduce the investors’ interests to invest, and they may cause the fall of the share price.

Once again, it appears that there is a tug of war between factors which can increase the share price and factors which can decrease the share price. This present research also shows that there is a balance of perceptions between investors who believe that the company is still in the stage of business development and those who believe that an increase in debts can put a burden on the company in the long run, and, therefore, the investors are not interested in buying the shares. Worse still, they may even sell their current shares instead.

The fourth hypothesis states that sales growth has a significant positive effect on share price. Sales growth reflects the investment success in the previous period, and it can be used to predict the sales growth in the next period. The high level of a company’s sales growth is an indicator that the company is able to run the business properly, and this positive indicator becomes the basis of investors’ argumentation to buy the company’s shares.

Table 4 shows the sales growth coefficient is -0.0018 in a negative number. This shows that the higher the sales is, the lower the share price is. The prob. is 0.3079 which is > 0.05. This fact proves that sales growth has no significant effect on share price; thus, the fourth hypothesis is rejected. The result of this present research also confirm the assumption that high sales growth is considered as a burden for the company. Essentially, high sales growth is not identical with high income. For new products or products with low market attractiveness, it would take tremendous efforts to make the products be recognized and demanded by the market. One of the common efforts is to apply certain promotion strategies which, of course, need a lot of money. Another way to boost sales growth is by giving discounts. This is commonly used by companies to reach the short term objectives, i.e. to meet the sales target. However, Jackson & Wilcox (2000) assert that this discount policy will result in negative long-term effects to the company because by giving discounts, the buyers get higher bargaining power. They will be accustomed to this discount policy, and they will buy the products only if they are sold at a discount. Furthermore, by applying this discount policy, the company is led into a price competition with other similar companies. In the long run, the discount policy will inevitably entrap the company further into a financial problem as the policy will reduce its earnings. From this perspective, it is reasonable that some investors do not consider sales growth as one of the determinants of their investment decisions.

The fifth hypothesis states that profitability has a significant positive effect on share price. The higher the earnings of a company are, the more obvious it is
that the company is well-managed and efficient. It is also obvious that the company has the potential for reaping high earnings in the future. This kind of perception becomes the basic motivation for the investors to buy the shares, and this will cause an increase in the share price.

In Table 4, the ROA coefficient is 0.0293 which indicates that profitability has positive effect on share price. The Prob. is 0.0145 which is lower than 0.05 parameter. Thus, it can be concluded that profitability has a significant positive effect on share price, and the fifth hypothesis is accepted. A company with higher ROA indicates that the company is able to utilize its assets to generate earnings which means high ROA can increase profitability or the company’s earnings. Companies with high ROA will increase the investors’ trust and attract investors to invest money in the companies’ shares. The more investors make investments in a company, the higher the share price of the company will be.

To test the role of profitability as the intermediating variable of share price dynamics, this present research used Sobel test. The standard formulation of the Sobel test is as follows.

\[ Z = \frac{ab}{\sqrt{(b^2 \text{SE}_a^2) + (a^2 \text{SE}_b^2)}} \]

Where:
- \( a \) = regression coefficient of the independent variable against the mediating variable
- \( b \) = regression coefficient of the mediating variable against the independent variable
- \( \text{SE}_a \) = standard error of estimate from the effect of the independent variable on the mediating variable
- \( \text{SE}_b \) = standard error of estimate from the effect of the mediating variable on the dependent variable

The first test placed the profitability variable as the mediating variable on the effects of capital structure on the share price. The results is as follows.

\[ Z = \frac{0.0018 \times 0.0293}{\sqrt{(0.0293^2 \times 0.0039^2) + (0.0018^2 \times 0.0115^2)}} \]

\[ Z = 0.4541 \]

Using the same equation, Z value is estimated to test the effect of sales growth on the share price with profitability as the mediating variable. The result is shown as follows.

\[ Z = \frac{0.0028 \times 0.0293}{\sqrt{(0.0293^2 \times 0.0026^2) + (0.0028^2 \times 0.0115^2)}} \]

\[ Z = 0.9920 \]

From the Sobel test, the Z from each test is 0.4541 and 0.9920 respectively as they are used to test the role of profitability as the mediator of capital structure and sales growth effects on the share price. The values are below 1.98 with significance level at 5%. Thus, it can be concluded that profitability and sales growth do not mediate the effects of capital structure on share price. This means hypothesis six and hypothesis seven are rejected.

V. CONCLUSION

Based on the discussion, an empirical conclusion which can be drawn from this present research is that, partially, capital structure and sales growth have no significance effects on profitability and share price. However, the findings confirmed that profitability has significant effects on share price. The present research also studied profitability as the mediating variable between capital structure and sales growth on share price. The findings show that profitability does not mediate the effects of capital structure and sales growth on share price.

The findings confirm the indication that the earnings variable or profit is an important variable which needs to be taken into consideration when investors want to invest in certain shares. Companies should take specific measures to increase their abilities to generate earnings because earnings affect the increase of the companies’ value and the shareholders’ well-being. Therefore, the companies should apply suitable strategies to control various internal factors which can affect the companies’ abilities to generate earnings, including the ability to control costs (e.g. interest expenses).
